

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

and the living, rather than of the didactic and the transcendental, that he is perennial and immortal.

APPLETON MORGAN.

LETTERS TO THE EDITOR.

**** Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.*

The editor will be glad to publish any queries consonant with the character of the journal.

On request, twenty copies of the number containing his communication will be furnished free to any correspondent.

Kiowa County, Kan., Meteorites.

A REMARKABLE fall of meteorites of unknown date in Kiowa County, Kan., has recently been brought to the knowledge of the scientific world. Many of the citizens of Greensburgh, the county seat, were aware of the existence of these strange irons, and commonly called them meteoric; but there seems to have been no suspicion of their true character and value. Indeed, until the 17th of March, 1890, a specimen weighing 101.5 pounds had ornamented the sidewalk in front of a real estate office in the above-named town for about three years. The farmers in the vicinity of the locality where the fall had occurred had put some of the specimens to various uses.

They were first observed by cowboys, long before that portion of Kansas was open to settlement, while it was still a portion of the unrestricted cattle-range of western Kansas. The specimen before referred to, with two others of somewhat smaller size, had been removed from its original location by a cowboy, and buried at the head of a gulch about a mile distant. The cowboy had intended to carry the irons to Green's stage station, about eight miles distant, but was unable to transport so heavy a weight upon his pony. This was in 1885. The town of Greensburgh was laid out in that year, before the close of which the cowboy was taken sick, and died. Before his death, however, he informed two or three citizens of Greensburgh of his burial of the three strange stones. These citizens, about a year later, searched for and found the meteorites, bringing them in to Greensburgh.

Professor F. W. Cragin of Washburn College was the first scientific man who visited the farm upon which these masses had fallen, this visit occurring on March 13. He secured from one of the farmers five meteorites, aggregating in weight over a thousand pounds, the heaviest specimen weighing 466 pounds.

Professor Robert Hay arrived on the spot March 14, but did not obtain any specimens. The writer reached the interesting locality on March 17, and obtained one of the Greensburgh specimens which had just been secured by the farmer. He made a second visit on the 22d, securing the two remaining Greensburgh specimens, thus obtaining all three of the masses which had been removed by the cowboy. He made a third visit March 29, securing two other specimens, which had been obtained by the farmer from his neighbors. The weights of these five specimens are respectively 101.32, 71.50, 54.96, 52.82, and 35.72 pounds. These weights have been accurately determined (except that of the 71.50-pound mass) by the United States standard scales in charge of the Department of Physics in the University of Kansas.

The writer retains the 54.96-pound specimen for the Museum of the University of Kansas, the four others being now in the possession of Mr. George F. Kunz of New York City, who has also secured four of the five specimens obtained by Professor Cragin.

The total number of masses included in this fall was at least twenty. Two of them are in the possession of Professor N. H. Winchell of the University of Minnesota, and several have disappeared from view, either having been mislaid or being still in private hands. The total weight of all the masses must have exceeded two thousand pounds. They fell within an oval area about one mile in length.

The most remarkable point connected with the history of these meteorites is the fact that for five years they should have been known to so many citizens of Kiowa County before the attention of scientific men was directed to them. The wife of the farmer upon whose premises most of them were found persistently main-

tained that they would prove to be of some pecuniary value. This idea was, however, ridiculed by her relatives and neighbors; but she persisted in retaining control of most of the masses found upon the land pre-empted by her husband, until now the proceeds of this "iron from heaven" have cleared the farm from a heavy mortgage, and placed the family in comfortable circumstances.

These masses, during the period preceding their discovery by Kansas scientists, were put to a great variety of ignoble uses. One 75-pound specimen was used to keep in place the cover of a rain-barrel or the door of a cellar; another, weighing 350 pounds, served to hold down the roof of a stable; another, weight 210 pounds, was employed to secure the roof of a dug-out; another had been used with other common rocks to help fill up a hole under a barb wire fence through which the hogs had made their escape from their feeding-ground. This was the 35.72-pound specimen obtained on the writer's last visit, and was secured only after a long and anxious search.

Some of these specimens were only partially buried in the ground; others were struck by the breaking plough at a depth of from three to four inches; others at the second ploughing, five or six inches deep; others yet, by the stirring plough at the third ploughing in a subsequent season.

The specimen retained by the university weighed 54.96 pounds, or 24.93 kilos. It is an irregular plum-shaped mass, much pitted, and covered with a burned and weathered crust. Its extreme length is about eleven inches, and its breadth is seven inches. This specimen, as well as the others mentioned above, so far as examined by the writer, belongs to that class of meteoric iron known as "pallasite." It is composed of nickeliferous iron, including many cavities throughout the entire interior. These cavities are filled with troilite and a yellowish, glassy mineral, which is probably olivine. Some of the latter is very dark and less transparent.

The specific gravity, determined by Mr. E. C. Franklin, our assistant in chemistry, and obtained by weighing the whole mass, is 4.76. Two hundred and ninety-three grams have been removed from the larger end of the specimen, and a polished surface of about fifteen square inches has been obtained, which shows very well the structure. The Wiedmanstaeten figures, rather coarse in outline, were developed readily upon the polished iron surface by the application of nitric acid. The portion removed from the specimen is being used for analysis by Professor E. H. S. Bailey and Mr. E. C. Franklin, and the results of the analysis will appear later.

Lawrence, Kan., May 1.

Experiments with Cave-Air.

GRAND AVENUE CAVE is situated in Edmondson County, Ky., four miles from Mammoth Cave, on the Mammoth Cave Railway, and belongs to the system of great caves which are found in this section of the subcarboniferous limestone formation. Its extent has not been determined as yet, though from three to five miles are opened, showing a magnificent series of the grandest avenues to be found on the globe. The main avenue is about two miles long, and will average 40 feet wide and 30 feet high. This being the highest cave in this section makes it the driest in the rainiest seasons. The floors are covered with dust; but the absolute dryness of the air is best shown by a small house that was built in the cave some eighteen years ago, the wood, nails, lock, and hinges of which are as sound and bright as when first put in. - A self-registering thermometer placed in the cave last November has registered 50° ever since, that being the unvarying temperature. Investigations looking to the use of this cool, dry, and pure air have been in progress for the past six months. A shaft 5 inches in diameter and 225 feet deep was sunk into the cave at a distance of 1,500 feet from its mouth, over which a small experimental building was placed. By means of a small Sturtevant exhaust fan, the air from the cave was brought into the room, and the temperature was reduced from 72° to 59° in less than an hour, thereby showing very clearly that with a large shaft, by which the friction would be greatly reduced, any quantity of this air can be distributed through a large building, thus placing it within the power of the owners to absolutely control the climatic conditions
